The initiation of conidiophore development in the filamentous fungus *Aspergillus nidulans* is a complex process requiring the activities of several genes including *fluG*, *flbA*, *flbB*, *flbC*, *flbD*, and *flbE*. Recessive mutations in any one of these genes result in greatly reduced expression of the *brlA* developmental regulatory gene and a colony morphology described as fluffy. These fluffy mutants have somewhat diverse phenotypes but generally grow as undifferentiated masses of vegetative hyphae to form large cotton-like colonies. In this paper we describe a genetic screen to identify dominant mutations resulting in similar fluffy colony morphologies. We have identified 36 dominant fluffy mutant strains and shown that 29 of these mutants have greatly reduced *brlA* expression as compared to wild-type. In addition, we have found that 19 of these mutants are not only developmentally altered but also fail to produce the toxic, carcinogenic, *secondary metabolite* sterigmatocystin. At least three of the mutants isolated result from dominant activating mutations in *fadA* which encodes the α subunit of a heterotrimeric G-protein. Another of the mutants results from a dominant interfering mutation in *brlA*. We discuss the approaches taken to characterize these potentially important regulators of growth, development and secondary metabolism.

DESCRIPTORS:

G proteins; Transcription factor; Sporulation; Microbial development; Mycotoxin

CLASSIFICATION CODE AND DESCRIPTION:

85.7.17.3 - APPLIED MICROBIOLOGY AND BIOTECHNOLOGY / MICROBIAL METABOLISM AND PHYSIOLOGY / Microbial Physiology / Sporulation

LANGUAGES: English SUMMARY LANGUAGES: English

NO. OF REFERENCES: 46

The beta-lactam antibiotic, penicillin is produced as end product by only some filamentous fungi, most notably by *Aspergillus nidulans* and *Penicillium chrysogenum*. The biosynthesis of this *secondary metabolite* is catalyzed by three enzymes which are encoded by the following three genes: *acvA* (*pcbAB*), *ipnA* (*pcbC*) and *aat* (*penDE*). The genes are organized into a gene cluster. In *A. nidulans*, several studies have indicated that the genes are controlled by a complex regulatory network. The wide-domain regulatory protein PACC binds to the intergenic region between *acvA* and *ipnA* and, at alkaline pH, increases at least *ipnA* gene transcription. An additional DNA binding protein (PENR1) was suggested to repress *acvA* and to activate *ipnA* and *aat* expression. Furthermore, three recessive trans-acting mutations have been characterized (*prgA1*, *prgB1*, *npeE1*) which most likely correspond to positively acting regulatory genes of the penicillin biosynthesis genes.

DESCRIPTORS:

Aspergillus *nidulans*; penicillin biosynthesis; beta-lactam biosynthesis;

Penicillium chrysogenum; secondary metabolism; peptide synthetase

Document type: JOURNAL ARTICLE; REVIEW; REVIEW, TUTORIAL

JOURNAL ANNOUNCEMENT: 9910

Subfile: INDEX MEDICUS

Microbial *secondary* *metabolite* production is frequently associated with developmental processes such as sporulation, but there are few cases where this correlation is understood. Recent work with the filamentous fungus *Aspergillus* nidulans has provided new insights into the mechanisms coordinating production of the toxic *secondary* *metabolite* sterigmatocystin with asexual sporulation. These processes have been shown to be linked through a common need to inactivate a heterotrimeric G protein dependent signaling pathway that, when active, serves to stimulate growth while blocking both sporulation and sterigmatocystin biosynthesis. (38 Refs.)

Descriptors: *Aspergillus* nidulans--Physiology--PH; *Gene Expression Regulation, Fungal; *Sterigmatocystin--Biosynthesis--BI; *Aspergillus* nidulans--Genetics--GE; *Aspergillus* nidulans--Metabolism--ME; Genes, Fungal; Reproduction--Physiology--PH; Spores, Fungal--Genetics--GE; Spores, Fungal--Physiology--PH

CAS Registry No.: 10048-13-2 (Sterigmatocystin)

DOCUMENT TYPE: Article
LANGUAGES: English SUMMARY LANGUAGES: English

Expression of ras has been correlated with increased intrinsic resistance
to ionizing radiation. In this study we show that increased EJras
expression in human cells is associated with a decrease in the frequency of
radiation-induced micronuclei. The experimental system consisted of human
osteosarcoma-derived cell lines which quantitatively vary in their EJras
expression. There was a dose-dependent relationship between radiation dose
and micronuclei formation in all cell lines tested. Human osteosarcoma
cells, in which the ras level was undetectable, had the highest frequency
of micronuclei production at all radiation doses tested. At 4 Gy the most
radioresistant cells exhibited a 41.5 +/- 5% decrease in the production of
micronuclei concomitant with high ras expression in comparison with the
relatively radiosensitive parental cell line. Cells expressing a low amount
of EJras demonstrated a 23 +/- 3% decrease in micronuclei induction
compared with parental cells. Treatment of cells with *lovastatin*, an
inhibitor of ras-encoded p21(ras) post-translational processing via the
mevalonate pathway, markedly decreased the *yield* of micronuclei formation
in cells transfected with ras; the drug had no effect on radiation-induced
micronuclei formation in parental cells. The use of the in vitro
micronuclei assay has provided a convenient way to visualize differences in
the genotoxic damage induced by ionizing radiation in cells which express
different amount of EJras. The results indicate that elevation of ras
expression in human cells can lead to a decrease in the number of
radiation-induced micronuclei formed and that this relationship is
dependent on membrane association of ras-encoded p21.
